

Validation Figure-5 comparison: E-net target vs no augmentation vs best augmented variant

Best augmented variant chosen by validation ΔR^2 : both_uncertainty_joint (ΔR^2 vs matched baseline = +0.157). For this variant, game-length interaction alignment improves slightly (+0.034) but contribution-framing alignment worsens materially (-0.633). Validation lacks the hidden + all-or-nothing + opt-in framing cell, so those line segments are incomplete.
